New proposal

Proposal ID	26130004
Title	Ultrafast Laser-Induced Phase Transitions in 2D Materials for Quantum Device Applications
Abstract	Two-dimensional (2D) materials such as MoS and WS exhibit unique electronic and optical properties that make them promising candidates for next-generation quantum and optoelectronic devices. This experiment aims to investigate ultrafast laser-induced phase transitions in monolayer and few-layer 2D materials using femtosecond pump-probe spectroscopy at the LSF. By employing the high-repetition-rate femtosecond laser systems available at the CLF, we will induce and monitor non-equilibrium phase transitions in real time. The experiment will focus on the transition between semiconducting (2H) and metallic (1T) phases, which can be triggered by ultrafast excitation. Time-resolved reflectivity and transient absorption measurements will be used to capture the dynamics of carrier relaxation, lattice distortion, and phase evolution on femtosecond to picosecond timescales. The results will provide insights into the fundamental mechanisms of light-induced phase control in 2D materials and inform the design of ultrafast switches and memory elements for quantum technologies.
Principal Investigator	Jane Hollister (jane.hollister@stfc.ac.uk) (STFC) (UNITED KINGDOM)

The proposed access route is	Direct Access
Is this a resubmission?	No
The proposal falls under the following science programmes	Technical development
Research Grants	
Does this proposal have any industrial involvement/sponsorship?	No
Does your group have wider industry links not directly involving your present use of the Central Laser Facility?	No

Does your group have wider industry links not directly involving your present use of the Central Laser Facility?

No

Requirements

Technical Requirements (including details of the laser parameters and apparatus required)

Laser Configuration: A femtosecond Ti:Sapphire laser (e.g., 800 nm, 100 fs pulse duration) is used. The beam is split into pump and probe paths using a beam splitter. Pump-Probe Setup: The pump beam excites the sample, inducing a non-equilibrium state. The probe beam, delayed via a motorized delay stage, interrogates the sample at various time intervals post-excitation. Both beams are focused onto the same spot on the sample using a microscope objective. Detection: Changes in reflectivity and transient absorption are measured using fast photodiodes and spectrometers. Data is collected as a function of time delay to build a time-resolved map of the phase transition dynamics.

Technical Review

Status	Feasible
Comment	This is a technically rigorous and scientifically ambitious proposal that aligns well with the CLF's mission to support frontier research in ultrafast science. The experiment is expected to yield high-quality data, advance theoretical understanding, and contribute meaningfully to the development of quantum technologies. Strongly recommended for support.

New fap review

Review ID	4212
Comment	The proposed experiment represents a bold and visionary step at the intersection of ultrafast laser science, quantum materials research, and next-generation device engineering. By leveraging the world-class capabilities of the CLF, this project aims to unravel the fundamental mechanisms of laser-induced phase transitions in two-dimensional (2D) materials—an area of immense scientific and technological promise. What makes this proposal particularly compelling is its focus on ultrafast dynamics. The ability to probe and control phase transitions on femtosecond timescales opens a new frontier in understanding non-equilibrium states of matter. This is not only intellectually exciting but also critically important for the development of quantum devices that rely on precise manipulation of material phases. The choice of 2D materials is both timely and strategic. These materials exhibit rich phase diagrams and strong light-matter interactions, making them ideal candidates for ultrafast studies. The potential to induce and stabilize novel quantum phases using tailored laser pulses could lead to breakthroughs in quantum computing, neuromorphic systems, and low-power electronics. The experimental design is robust, combining state-of-the-art laser systems with advanced diagnostics and theoretical modeling. The team's interdisciplinary expertise ensures that the project is not only feasible but also poised to deliver high-impact results. Moreover, the alignment with national and international priorities in quantum technologies underscores the broader relevance and urgency of this work. In summary, this proposal is scientifically ambitious, technically sound, and strategically aligned with the future of quantum device innovation. It exemplifies the kind of high-risk, high-reward research that the CLF is uniquely positioned to support. I strongly endorse this experiment and look forward to the transformative insights it is likely to generate.

For all other queries please contact your FAP Secretary

The Central Laser Facility (CLF) at the Rutherford Appleton Laboratory is one of the world's leading laser facilities providing scientists from the UK and Europe with an unparalleled range of state of the art technology to carry out a broad range of experiments in physics, chemistry and biology. Our laser facilities range from advanced, compact tuneable lasers which can pinpoint individual particles to high power laser installations that recreate the conditions inside stars.
